

## II. CLAIM AMENDMENTS

1. (Currently amended) A system comprising a plurality of connected modules for and providing data communication between the connected modules, wherein individual ones of said modules are adapted-operative to transmit to and receive from one another of said modules a data package,

wherein said data package is a block of data or a data packet or a datagram, the data package being composed of a sequence of bits arranged in fields, the fields being disposed in a plurality of layers constituting comprising-in-a layered structure, a physical layer comprising:

a physical layer having a first segment and a second segment for encapsulating other ones of the layers in said data package layered structure, the physical layer serving to convey a bit stream through a network,

a data link layer comprising a data link layer control section for carrying data link layer control data and a data section for carrying data for said other layers, the data link layer being enclosed by the segments of said physical layer, and

a transport layer enclosed by the data link layer, the transport layer defining a message in said data section, which message is configured according to a transport layer protocol and comprises:

a payload and a first header field for format of said payload,

a second header field for start of said payload in said message,

a third header field for length of said message,

a fourth header field for version of said transport layer protocol, and

a fifth header field for message group identity establishing receiving resource format of said payload.

2. (Currently amended) A system according to claim 1, wherein individual ones of said modules comprise a mobile communication device such as a cell, mobile or satellite telephone, a personal digital assistant, or a peripheral thereto.

3. (Previously presented) A system according to claim 1, wherein said modules comprise one or more objects communicating said message with one another, and a data link layer generator and physical layer generator adapted to encapsulate said message according to a data link layer protocol and to a physical layer protocol, respectively.

4. (Previously presented) A system according to claim 1, wherein said transport layer further comprises a sixth header field for a message identity for uniquely identifying said payload.

5. (Previously presented) A system according to claim 1, wherein said transport layer comprises a seventh header field for a connection number for identifying a communicating object in said module.

6. (Currently amended) A system according to claim 1, wherein said transport layer comprises an ~~eight~~-eighth header field for a transaction identity for sequencing said message relative to other messages.

7. (Previously presented) A system according to claim 1, wherein said data link control data comprises a checksum field following said message.

8. (Previously presented) A system according claim 1, wherein said first segment of said physical layer comprises a media field for defining media, across which the data package is transferred.

9. (Previously presented) A system according to claim 1, wherein said first segment further comprises a synchronization field for synchronizing the receiving module with the transmitting module.

10. (Previously presented) A system according to claim 1, wherein said second segment of the physical layer comprises an index byte for providing the receiving module with information rewarding segmentation or partitioning of data contained in a message.

11. (Previously presented) A system according to claim 1, wherein said second segment further comprises a sequence and acknowledge field for providing a receiving module with information whether said data package is an acknowledgement message or an ordinary message.

12. (Currently amended) A system according to claim 1, wherein said second segment further comprises a sequence and an acknowledge field, and is adapted to inform whether an error was identified in the received data package, when said data package is an acknowledgement message.

13. (Previously presented) A system according to claim 11, wherein said sequence and acknowledgement field is further adapted to inform a receiving module that a sequence number in said receiving module should be reset.

14. (Previously presented) A system according to claim 11, wherein said sequence and acknowledgement field is adapted to recognise acknowledgement messages and detect missing data packages.

15. (Previously presented) A system according to claim 1, wherein said second segment further comprises a fill field for ensuring that all data packages sent over said port connector contain an even amount of bytes.

16. (Previously presented) A system according to claim 1, wherein said second segment further comprises a parity field for storing parity calculated on the basis of the data package excluding the parity field.

17. (Previously presented) A system according to claim 1, wherein said transport layer comprises a ninth header field for a future extension comprising information required by a future transport layer protocol.

18. (Currently amended) A data package for communicating between modules of a modular system, wherein said data package is provided by a signal having in a block of data or a data packet or a datagram, the data package being composed of a sequence of bits arranged in fields, the fields being disposed in a plurality of layers constituting a layered structure, physical layer data comprising:

a physical layer having a first segment and a second segment for encapsulating other ones of the layers in said data package layered structure, the physical layer serving to convey a bit stream through a network,

a data link layer comprising a data link layer control section for carrying data link layer control data and a data section for carrying data for said other layers, the data link layer being enclosed by the segments of said physical layer, and

a transport layer enclosed by the data link layer, the transport layer defining a message in said data section, which message is configured according to a transport layer protocol and comprises:

a payload and a first header field for format of said payload,

a second header field for start of said payload in said message,

a third header field for length of said message,

a fourth header field for version of said transport layer protocol, and

a fifth header field for message group identity establishing receiving resource format of said payload.

19. (Previously presented) A data package according to claim 18, wherein said transport layer further comprises a sixth header field for a message identity for uniquely identifying said payload.

20. (Previously presented) A data package according to claim 18, wherein said transport layer comprises a seventh header field for a connection number for identifying a communicating object in said module.

21. (Previously presented) A data package according to claim 18, wherein said transport layer comprises an eighth header field for a transaction identity for sequencing said message relative to other messages.

22. (Previously presented) A data package according to claim 18, wherein said transport layer comprises a ninth header field for a future extension comprising information required by a future transport layer protocol.

23. (Previously presented) A receiver unit adapted to receive a data package according to claim 18.

24. (Previously presented) A transmitter unit adapted to transmit a data package according to claim 18.

25. (Currently amended) A method for establishing data communication between modules of a modular system via communication of, ~~wherein said modules each communicate a data package, comprising: in wherein said data package is a block of data or a data packet or a datagram, the data package being composed of a sequence of bits arranged in fields, the fields being disposed in a plurality of layers constituting a layered structure, the method comprising:~~

providing a physical layer comprising a first segment and a second segment for encapsulating other ones of the layers in said data package layered structure, and the physical layer serving to convey a bit stream through a network,

providing a data link layer comprising a data link layer control section for carrying data link layer control data and a data section for carrying data for said other layers, the data link layer being enclosed by the segments of said physical layer, and wherein

said method comprises: providing in said data package in a transport layer enclosed by the data link layer, the transport layer defining a message in said data

section, which message is configured according to a transport layer protocol and comprises:

a payload and a first header field for format of said payload,

a second header field for start of said payload in said message,

a third header field for length of said message,

a fourth header field for version of said transport layer protocol, and

a fifth header field for message group identity establishing receiving resource format of said payload.

26. (Currently amended) A storage medium having therein a computer program comprising code for operating a data processor to establish data communication among a plurality of modules of a modular system by a sequence of steps, ~~between a plurality of modules, wherein said~~ comprising:

communication by each of the plurality of modules each communicating a data package, comprising in wherein said data package is a block of data or a data packet or a datagram, the data package being composed of a sequence of bits arranged in fields, the fields being disposed in a plurality of layers constituting a layered structure, having a physical layer comprising

providing in the data package a physical layer comprising a first segment and a second segment for encapsulating other ones of the layers in said data package layered structure, the physical layer serving to convey a bit stream through a network, and

providing in the data package a data link layer comprising a data link layer control section for carrying data link layer control data and a data section for carrying data for said other layers, the data link layer being enclosed by the segments of said physical layer, and

~~wherein said program provides~~providing in said data package a transport layer enclosed by the data link layer, the transport layer defining a message in said data section, which message is configured according to a transport layer protocol and comprises:

a payload and a first header field for format of said payload,

a second header field for start of said payload in said message,

a third header field for length of said message,

a fourth header field for version of said transport layer protocol, and

a fifth header field for message group identity establishing receiving resource format of said payload.
